# Why Neural Networks?

Point Group  
Equivariant  
Networks for  
Material Systems

Physics assumes there exists a map between configurations and properties of physical systems:

$$\{\vec{r}_i\} \xrightarrow[\text{Nature}]{} \{\vec{r}'_i\}$$

Neural network techniques assume maps between abstract input and output spaces exist:

$$X \xrightarrow[\text{Neural Network}]{} Y$$

and that these may be expressed in a basis of adequately large neural networks.

But how do we apply this to material systems?

# Machine Learning on Crystal Systems

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

To perform predictive tasks for material systems, such as crystalline structures, we essentially need two things:

- A way to represent the material system mathematically
- A trainable predictive model or set of functions which takes, as input, the material system's representation (as well as a large set of data)

# Usual Crystal Graph Construction (a la CGCNN)

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Graph Neural  
Networks

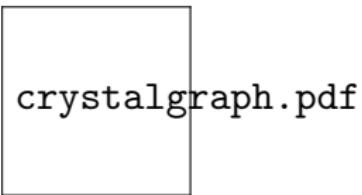

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

The usual technique is to represent crystalline systems as graphs (nodes and edges), with atomic features associated with nodes and geometric features associated with edges

Graph Neural  
Networks

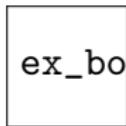

Crystal Hypergraphs

O(3)-Equivariant  
Networks

Tensor Prediction

Material Symmetry

$$m_i^{t+1} = \sum_{n_j \in \mathcal{N}(i)} M_t(n_i^t, e_{ij}, n_j^t)$$

$$n_i^{t+1} = U_t(n_i^t, m_i^{t+1})$$

Here, each node  $n$  from layer  $t$  to  $t + 1$  is updated according to an update function  $U$ , which takes as input messages formed from each pair of nodes containing the node to be updated.

Problem: Our underlying representation encodes only distances between atoms!

crystalgraph\_cntex.pdf

So, as a rough example, the above two crystalline structures would have the same representations!

# Solution: Hypergraphs!

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

hyperedge\_ex.pdf

This gives us a natural way to encode features with higher order structure, where hypergraph nodes still represent atoms of underlying crystal structure.

Can treat all different order structures in crystals on equal footing: each has a corresponding hyperedge with a feature

# Local Environments as Hyperedges

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Considering our previous problem, we can now encode this lost geometrical information in larger hyperedges:

`motiflevel_ex.pdf`

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

This geometrical information can be encoded quantitatively with continuous symmetry measures, local structure order parameters, etc., depending on task

# Extending Message Passing to Hypergraphs

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

Now, we need a suitable convolutional structure that applies to hypergraphs...

In this case, the neighborhood of nodes relevant to each message are now a set (instead of the single neighboring node feature of classic MPNNs)

$$m_i^{t+1} = \sum_{h_j \ni x_i} M_t(n_i^t, \underbrace{h_j^t, \{n_w^t | n_w \in h_j\}}_{e_{ij}, n_j})$$

$$n_i^{t+1} = U_t(n_i^t, m_i^{t+1})$$

# Hypergraph Convolution

To deal with the variable sized neighborhoods of features, we simply aggregate the neighborhood features in the message passing phase, so that we essentially have the following form of convolution:

$$\begin{aligned}x_i \rightarrow x_i + f_b(x_i \oplus e_{ij} \oplus \text{AGG}(\{x_i, x_j\})) \\+ f_m(x_i \oplus m_j \oplus \text{AGG}(\{n_w^t | n_w \in m_j\}))\end{aligned}$$

where we only consider pair-wise and local environment hyperedges above (with other order structures, such as triplet and unit cell level hyperedges also fitting into this framework). This allows us to effectively capture higher-order geometric features in an invariant manner!

But what if we care about coordinate-system dependent quantities?

# Equivariant Functions

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

An equivariant function  $f : X \rightarrow Y$ , where  $X, Y$  are vector spaces, is one that 'commutes' with a group's actions, satisfying:

$$f\left(\mathcal{D}^X(g)x\right) = \mathcal{D}^Y(g)f(x)$$

Tensor products are equivariant with respect to their argument vector spaces.

Equivariance is always with respect to some group of transformations!

# Why Equivariant Functions?

Point Group

Material Systems

Alex Heilman

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

Physical processes respect coordinate system rotations  $R$ :

$$\{R\vec{r}_i\} \xrightarrow{\text{Nature}} \{R\vec{r}'_i\}$$

In general, neural networks do not:

$$RX \xrightarrow{\text{Neural Network}} ?$$

So what do we want?

# Equivariant Networks

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

We want equivariant networks for physics!

$$RX \xrightarrow[\text{Neural Network}]{\text{Equivariant}} RY$$

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

In equivariant networks, we consider feature vectors in basis of representation space as:

$$v_i^\alpha$$

with indexes  $\alpha$  denoting the irrep it transforms as, and  $i$  denoting the dimension of irrep space  $\alpha$ .

# Equivariant Networks (cont.)

Compositions of equivariant functions are equivariant [?].  
We consider building blocks:

- ▶ Self-interaction:

$$v'_{nc} = W_c^i v_{ni}$$

- ▶ Non-linear functions along channels (for trivial irrep  $\alpha = 1$ ):

$$v'_{nc} = f(v_{nc} + b_{nc})$$

- ▶ Group correlation with filters [?]:

$$[F \star v](g) = \sum_{h \in G} \sum_c F_c(h) v_c(g^{-1}h)$$

- ▶ Tensor products with filters [?, ?]:

$$(v'_{nc})_n^\gamma = \sum_{ij} U_{\alpha i \beta j}^{\gamma n} (F_j^\beta \otimes V_i^\alpha)$$

- ▶ Pooling over nodes or channels:

$$v_c = \sum_n v_{nc}$$

# $SO(3)$ Properties

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Most modern equivariant networks are specifically  $SO(3)$ -Equivariant.

- ▶ Inifinite order  $\rightarrow$  infinite irreps
- ▶ Irreps are Wigner  $\mathcal{D}^\ell$  matrices
- ▶ Natural basis set  $Y_m^\ell$  of dimension  $d_\ell = 2\ell + 1$

Many models are further referred to as  $E(3)$ -equivariant for the Euclidean group (add parity and translation invariance).

# Tensor Field Networks

Point Group  
Equivariant  
Networks for

Material Symmetry

$$(v_{nc}^{L+1})_m^\ell = (v_{nc}^L)_m^\ell + \sum_{b \in \mathcal{N}(n)} \sum_{\ell_f m_f, \ell_i m_i}^{\ell_{\max}, m_{\max}} c_{\ell_f m_f \ell_i m_i}^{\ell_o m_o} (F_c^L(r_{nb}))_{m_f}^{\ell_f} (v_{bc}^L)_{m_i}^{\ell_i}$$

- ▶  $v_{nc}^L$ : Node feature of node  $n$ , channel  $c$ , layer  $L$
- ▶  $c_{\ell_f m_f \ell_i m_i}^{\ell_o m_o}$ : Clebsch-Gordan coefficients
- ▶  $F_c^L$ : Filter function (trainable)
- ▶  $r_{nb}$ : Radius between nodes  $n$  and neighbor  $b \in \mathcal{N}(n)$

$F$  is generally a neural network;  $r$  is often expanded with some radial basis function (RBF): Gaussian, Bessel, etc.

# $SO(3)$ -Equivariant Features

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Remember that node (and edge) features now have additional indices  $\ell$  and  $m$ !

$$(v_{nc}^{L+1})_m^\ell$$

This allows us to keep track of which components transform like which irreps of  $SO(3)$ .

But what can we do with this?

# $J_z$ Basis

Recall  $\ell = 1$  spherical harmonics (with Racah normalization):

$$Y_1^{+1} = -\frac{1}{\sqrt{2}}(x + iy) = \frac{1}{\sqrt{2}} \sin \phi e^{i\theta}$$

$$Y_1^0 = z = \cos \phi$$

$$Y_1^{-1} = -\frac{1}{\sqrt{2}}(x - iy) = \frac{1}{\sqrt{2}} \sin \phi e^{-i\theta}$$

So, define  $J_z$  basis:

$$\begin{bmatrix} a_+ \\ a_0 \\ a_- \end{bmatrix} = \begin{bmatrix} -\frac{1}{\sqrt{2}} & -\frac{i}{\sqrt{2}} & 0 \\ 0 & 0 & 1 \\ -\frac{1}{\sqrt{2}} & +\frac{i}{\sqrt{2}} & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

so that  $\hat{n} = a_+ Y_1^1 + a_0 Y_1^0 + a_- Y_1^{-1}$

# Clebsch-Gordon Expansion

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

Build larger spherical harmonic tensors with CG expansion:

$$Y_{\ell_1}^{m_1} \otimes Y_{\ell_2}^{m_2} = \sum_{L=-|\ell_1-\ell_2|}^{\ell_1+\ell_2} \sum_{M=-L}^L c_{\ell_1 0 \ell_2 0}^{L0} c_{\ell_1 m_1 \ell_2 m_2}^{LM} Y_L^M$$

where  $Y_L$  represents a  $2L + 1$  dimensional symmetric tensor space of rank  $L$ .

This serves as a relation between symmetric tensor's  $J_z$  basis components and higher order spherical harmonic tensors.

$$T^{(n)} = \underbrace{a_{\alpha\beta\dots}}_n (Y_1^\alpha \otimes Y_1^\beta \otimes \dots) \Rightarrow y_\ell^m Y_L^M$$

But, what about asymmetric tensors?

# $SO(3)$ Invariant Tensor Subspaces

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

We can always reduce an arbitrary tensor  $T$  that transforms under a transformation as:

$$T_{x_1 x_2 \dots x_n} \rightarrow T_{x'_1 x'_2 \dots x'_n} = R_{x'_1}^{x_1} R_{x'_2}^{x_2} R_{x'_3}^{x_3} T_{x_1 x_2 \dots x_n},$$

into a set of irreducible (but not necessarily unique) symmetric,  $SO(3)$  invariant subtensors:

$$\{h^{(\ell)}\} \rightarrow \{h'^{(\ell)}\} = \{\mathcal{D}^\ell(R)h^{(\ell)}\}$$

This decomposition can be constructed by consecutive decomposition with respect to  $GL$  and then  $O$  and  $SL$

$$SO = SL \cap O \subset GL$$

# $SO(3)$ Invariants Ex.: Rank 2

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Consider a rank-two tensor  $E_{ij}$ :

Decompose into symmetric  $S$

$$S_{ij} = \frac{1}{2}(E_{ij} + E_{ji})$$

Then take trace  $t = g_{ij}S_{ij}$  and residue  $R = S - tg$ .

And, antisymmetric  $A$ :

$$A_{ij} = \frac{1}{2}(E_{ij} - E_{ji})$$

# Point Group Properties

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Groups of operations that leave at least one point fixed and are compatible with a Bravais lattice.

Point groups (in 3D) have following properties:

- ▶ 32 crystallographic point groups in 3D
- ▶ Finite number of irreps for each
- ▶ All irreps of point groups are of dimension  $d_\alpha = 1, 2, 3$
- ▶ All allow a (often reducible) 3D representation
- ▶ Decompositions with  $c_{\alpha\beta\gamma} = 0, 1, 2$

(Point group representations may be used to generate induced representations of space groups)

# Site-symmetry Equivariant Networks

Equivariant  
Networks for  
Material Systems

Alex Heilman

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

Index vectors by  $\alpha, i$  from site-symmetry group instead!

$$(v_{nc}^{L+1})_m^\ell = (v_{nc}^L)_n^\gamma + \sum_{b \in \mathcal{N}(n)} \sum_{\alpha i, \beta j} U_{\alpha i \beta j}^{\gamma n} (F_c^L(r_{nb}))_j^\beta (v_{bc}^L)_i^\alpha$$

- ▶ Natural cutoff (finite summation over  $\alpha, \beta$ )
- ▶ Natural readout for symmetric properties ( $\gamma = 1$ )
- ▶ Accounts for all physical symmetry but not more

# Coupling Coefficients

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Coupling coefficients for point groups can be computed from irreps with Dirl's Formula [?]:

$$(U_{\alpha i \beta j}^{\gamma n})^m = \sqrt{\frac{d_\gamma}{N_G}} \left[ \sum_{g \in G} \Gamma_{qq}^\alpha(g) \Gamma_{ss}^\beta(g) \Gamma_{aa}^{\gamma\dagger}(g) \right]^{-\frac{1}{2}} \cdot \sum_{g \in G} \Gamma_{iq}^\alpha(g) \Gamma_{js}^\beta(g) \Gamma_{na}^{\gamma\dagger}(g)$$

With these models we can predict:

- Scalar quantities that are invariant under material symmetry group (not just spherically symmetric)
- Tensor quantities that respect material symmetry
- Symmetry-adapted Hamiltonian elements

# Hamiltonian Group

We define the operator  $\hat{O}_G$  to be a representation of a group  $G$  that acts on  $H$ 's input space  $\vec{r}$  as:

$$\hat{O}_G(g)\hat{H}(\vec{r}) = \hat{H}(g^{-1}\vec{r})$$

The "group of the Hamiltonian" is the largest group of the form above that commutes with the Hamiltonian.

$$[\hat{H}, \hat{O}(g)] = 0 \quad \forall g \in G$$

In such a case, the operators must have a simultaneous set of eigenvectors  $\psi_\alpha^k$  that span the space of functions:

$$f(\vec{r}) = \sum_{k,\alpha} c_k^\alpha \psi_\alpha^k = \sum_{k,\alpha} f_\alpha^k(\vec{r})$$

We have some freedom in choice of this set of basis functions on which the linear operators of the representations act.

# Hydrogen Orbitals

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

Graph Neural  
Networks

Crystal Hypergraphs

$O(3)$ -Equivariant  
Networks

Tensor Prediction

Material Symmetry

The Hydrogen Hamiltonian  $\hat{H}_H(\vec{r})$  for a non-relativistic electron has separable eigenfunctions:

$$\psi_i(\vec{r}) = R_i(r)\Omega_i(\theta, \phi)$$

Furthermore,  $\hat{H}_H$  commutes with  $SO(3)$  so these must be simultaneous with  $SO(3)$ :

$$[\hat{H}, \hat{O}(g)] = 0 \quad \forall g \in SO(3) \quad \Rightarrow \quad \psi_{nm}^{\ell}(\vec{r}) = R_n^{\ell}(r)Y_m^{\ell}(\theta, \phi)$$

(where  $R$  is also indexed by  $\ell$  due to an 'accidental' symmetry)

- ▶  $\theta, \phi$  dependence determined by group theory
- ▶  $r$  dependence determined by specific form of  $\hat{H}_H$

# Tight-Binding Approximations

Point Group  
Equivariant  
Networks for  
Material Systems

Alex Heilman

In simplest form, consider H-like orbitals  $|\psi_{nmp}^\ell\rangle$  localized at points  $p$  as basis for many particle system defined by  $\hat{H}$  so:

$$\hat{H}_{nmpl,jkhI} = \langle \psi_{jkh}^I | \hat{H} | \psi_{nmp}^\ell \rangle$$

Now, we can incorporate point group symmetry of crystal and molecular sites by directly learning features associated with basis functions that transform as irreducible representations.
